Abstract—Blockchain has become a key technology in a plethora of application domains owing to its decentralized public nature. The cyber-physical systems (CPS) is one of the prominent application domains that leverage blockchain for myriad operations, where the Internet of Things (IoT) is utilized for data collection. Although some of the CPS problems can be solved by simply adopting blockchain for its secure and distributed nature, others require complex considerations for overcoming blockchain-imposed limitations while maintaining the core aspect of CPS. Even though a number of studies focus on either the utilization of blockchains for different CPS applications or the blockchain-enabled security of CPS, there is no comprehensive survey including both perspectives together. To fill this gap, we present a comprehensive overview of contemporary advancement in using blockchain for enhancing different CPS operations as well as improving CPS security. To the best of our knowledge, this is the first paper that presents an in-depth review of research on blockchain-enabled CPS operation and security.

Index Terms—Blockchain, Cyber-physical systems, Data security, Internet of Things

I. INTRODUCTION

Cyber-Physical Systems (CPS) have become essential for critical infrastructure worldwide, including water, energy, gas, healthcare, transportation, and smart grid systems. These systems include Internet of Things (IoT) devices that generate a massive volume of data, which they communicate to a centralized system. However, these devices have resource constraints for data storage, processing, and security measures, which pose significant challenges for the security and efficiency of CPS. As attackers are increasingly carrying out more directed attacks, CPS have become important targets to achieve maximum impact. A recent example of the far-reaching impacts of an attack on CPS is the recent Colonial Pipeline malware attack [1]. This heightens the global importance of effective CPS security solutions. As the number of these interconnected devices continues to grow, with an estimated 29.3 billion networked devices by 2023 [2], blockchain has emerged as a significant component in restructuring CPS systems for increased security and efficiency, as shown in Fig. 1.

Blockchain is regarded as one of the most important technologies that will bring about the next society transformation into the future [3]. Decentralization, immutability, distributed trust, increased security, smart contracts, digital currency, faster settlements, and minting are all properties of blockchain that can be utilized to address different challenges of CPS. To include in shared transactions with tamper-proof records, IoT devices/CPSs will be able to transfer the data to blockchain

that is private in nature. Owing to the blockchain's distributed replication, diverse CPS data users can supply data from IoT sources without the requirement for core management and control systems. Each transaction may be verified by all the stakeholders belonging to the ecosystem of the CPS, avoiding disagreements and guaranteeing that each user is accountable for his particular parts in the entire transaction. Although solutions provided by blockchain are being adopted widely in the contemporary CPS domains, because of the different capabilities discussed, there are a lot of challenges in meeting the diverse requirements of different CPS applications.

Fig. 1. Blockchain enabling CPS operations and security.

From the literature, it is observed that a lot of the blockchain-based security and operation surveys have been conducted in the CPS domain. However, the review focus was limited to specific considerations for either the operation or the security of CPS achieved through leveraging blockchain. In this work, we provide a detailed review of the research works conducted in the blockchain-enabled CPS domain from both the perspectives, and to the best of our knowledge, this is the first paper with this level of exhaustive overview of blockchain-enabled CPS.

The rest of the paper is organized as follows: We provide sufficient preliminary information in Section II. The related works are discussed in Section III. We discuss the literature related to Blockchain-enabled CPS in Section IV. We present a statistical analysis of the literature in Section V. Lastly, we conclude the paper in Section VI.

II. BACKGROUND

In this section, we provide some introductory information regarding both CPSs and blockchain.

A. Cyber-Physical Systems

The concept of CPS is based on systems that incorporate both cyber and physical systems to exchange data in real time. A CPS is a network of embedded systems consisting of sensors, aggregators, and actuators that are capable of monitoring and controlling real IoT-related processes and objects [4]. CPS consists of the integration of sensing, networking, communication, control, and computation.

B. Blockchain

Blockchain is a decentralized and distributed method of recording and tracking digital interactions [5]. Zhao [6] describes how blockchain utilizes a chain-like data structure, which operates on a peer-to-peer network without a centralized trusted authority, and uses cryptography such as cryptographic hash and public-key cryptography. Each block contains various transactions, and blocks are chained together and have great redundancy. Therefore, if any blocks are altered or removed, this can easily be identified, and this also makes it very difficult to damage information on the blockchain. Furthermore, blockchain uses the Proof of Work (PoW) algorithm, which is used to validate transactions and create new blocks on the chain through solving a complex mathematical puzzle [6].

III. RELATED WORKS

A vast number of review articles on blockchain-enabled CPS have been published, each covering a distinct component of this research methodology. Many of these surveys focus on CPS security, like Taylor et al. identified peer-reviewed literature regarding cyber security through blockchain by exploring various adopted blockchain security applications in [7]. They highlighted the potentials of different research studies in the cybersecurity domain, even excluding the IoT, by blockchain applications. Gupta et al. offered a survey in [8] that is primarily concerned with the cybersecurity vulnerabilities of smart contracts in blockchain enabled CPS applications, where software code can be easily hacked by the adversarial users. Keshk et al. [9] provide a survey of current privacy-preserving techniques that are used to protect CPS systems and their data from cyber-attacks. They classify and explain privacy protection techniques, including blockchain.

Others focus on control and operation of blockchain-based CPS. Zhao et al. dissected various blockchain-enabled CPS in terms of the operations and features utilized, and classified them according to the sensitivity and throughput in [6]. Kanhere addressed in [10] that, although a decentralized approach realizes the true potential of CPS taking the unique features into account, the application of blockchain for diverse CPS domains has its own complex challenges. Braeken et al. shed light into the technical and societal challenges, solutions and opportunities in various application domains combining the benefits of blockchain and cyberphysical system [11]. In [12], Bodkhe et al. explored the state-of-the-art consensus mechanisms, highlighting their strengths as well as weaknesses

in decentralized CPS applications, through a comprehensive analysis. A holistic survey of different CPS application domains including smart grids, health-care systems, and industrial production processes leveraging blockchain for robustness and reliability, has been presented in [13]. They additionally provide a mathematical model for determining if a certain application may benefit from the blockchain. Dedeoglu et al. addressed in [14] that high latency, low scalability and throughput, and computationally expensive consensus mechanisms greatly hinder the mass adoption of blockchain in the CPS application domain. Sicato et al. present a comprehensive review to identify weaknesses in CPS systems and/or offer recommendations for how to safeguard these systems using deep learning and blockchain techniques, in [15]. Finally, Kumar et al. present a systematic review of blockchain and CPS with IoT, in which they explain how to use blockchain to combat security attacks and threats, trust management, and privacy preservation issues by combining various cutting-edge techniques [16]. Tibrewal et al. discuss the security and privacy issues, challenges, threats, dangers, and attack scenarios associated with the expansion of cyber-infrastructure systems and services supplied by smart devices and their innovations, as well as accompanying blockchain-based solutions in [17].

Each of these studies sheds light on important considerations for the usage of blockchain in CPS. However, none of the existing studies provides a focus on the research trends in using blockchain for enhancing CPS in different operations as well as improving security of CPS.

IV. RESEARCH STUDIES

In the following section, we classify recent studies by their focus. All the studies are certainly interrelated, and many could apply to several of the categories. However, in classifying the studies, we highlight the key objectives identified by the authors in order to gain a better perspective on the principal points of interest in recent research trends.

A. Cyber-physical System Security

Several studies place particular focus on CPS security. To ensure data sources are authentic and reliable, in 2018, Fu et al. proposed using blockchain in CPS for an information security risk evaluation system in [18]. Later, in 2020, Wang et al. analyzed the CPS data storage's security risks and proposed to utilize an improved blockchain mechanism for securing the data in [19]. Rathore et al. proposed a secure deep learning (DL) method in [20] with blockchain for ensuring the cybersecurity of next-generation IoT CPS where decentralized, secure DL operations are performed at the edge nodes. Lastly, Maloney et al. designed a security automation system in [21] to deal with the operational security tasks and managing the security of CPS without repetitive duty through the integration of blockchain. Because of the legal and ethical implications of a patient's medical data, cybersecurity is a major issue in healthcare. To address this problem, Nguyen et al. proposed a secure intrusion detection system in [22], for CPS in the healthcare industry that uses blockchain-based data transmission and a classification methodology. To be able to comply

with policies that ensure the safety of all entities inside a Medical Cyber Physical Systems (MCPS), as well as to provide security measures to enforce cryptographic solutions, Tyagi et al. introduced a blockchain based decentralized e-healthcare application framework in [23], for personal data management that assures users own and have access to their information. Chen et al. designed a lightweight authentication mechanism for sensor/execution devices, users, and gateway nodes in MCPS based on blockchain technology [24]. Das et al. presented a new key management protocol based on blockchain technology in [25], for AI-enabled Industrial Cyber-Physical Systems (ICPS) that does security analysis as well as formal security verification and resists various potential attacks in an ICPS context. Gupta et al. proposed a novel framework in which the Attribute-based searchable encryption (ABSE) scheme's inherent computational cost is managed by running its computationally intensive tasks on the blockchain network, making the framework suitable for online storage and retrieval of personal health data in a typical loud-based cyber-physical system (CCPS) [26]. Kaur et al. describe a methodology based on software defined networking (SDN) and blockchain to handle two difficult concerns in electric vehicle (EV)-assisted smart grid (SG) ecosystems: privacy guarantee and power security. They use SDN's ability to manage the SG's complicated relationships between multiple subsystems [27]. Rahman et al. developed a blockchain-based system in [28] that assures security in the absence of existing public key infrastructure certificates. The contribution entails a unique implementation of multi-signature within a dependable blockchain consortium that is subject to data security and efficient storage. Latif et al. presented a new routing protocol for IoT networks in [29] that uses a cluster topology and a blockchain-based SDN controller. Finally, in 2022, Suhail et al. proposed a blockchain-based Digital Twins (DT) framework in [30] as trusted twins for Securing CPS (TTS-CPS). They demonstrate the practicality of the TTS-CPS architecture in a proof of concept using the automotive industry as a CPS use case. Lu et al. assess the necessity of integrating blockchain and CPS into the research of the air traffic management (ATM) system in [31].

B. Cyber-physical System Control

Control is an essential factor in CPS, which can be tuned up through blockchain. Tan et al. proposed a blockchain-based access control scheme for Cyber-Physical-Social System (CPSS) in [32], where a node's account address in the blockchain is utilized as the identification number for accessing the CPSS big data. Garamvolgyi et al. [33] focused on the control of CPS with the use of smart contracts. They proposed an approach in which smart contracts are produced from behavioral models, namely Unified Modeling Language (UML) statecharts, to coordinate the use of CPS elements. Afanasev et al. [34] considered the advantages and disadvantages of blockchain and smart contract for control, workflow event logging, and monitoring in a Cyber-Physical Production System network. They proposed a blockchain-based architecture and provided relevant use cases.

C. Cyberphysical System Trust

Given the importance of blockchain for establishing trust in CPS through decentralization and eliminating the middle man, it is no surprise that this research direction has been very active in the last few years.

In 2018, Machado and Frohlich [35] presented a split blockchain-based architecture for increasing trust and decentralization for IoT data in CPS by using three levels to develop a chain of trust and using semi-trusted remote storage. Yang et al. [36] presented a method of decentralized private data acquisition blockchain using an on-demand data transmission routing algorithm and M/M/1/k queuing model to meet the trust and time consumption demands of CPPS. Afanasev et al. [37] proposed the use of a blockchain network as a platform for a distributed decentralized network through the use of smart contracts for trustful communication between the nodes. Also, Gries et al. [38] discussed the idea of using blockchain technology for scalable and decentralized trustful information flow tracking for CPS, using Information Flow Monitor (IFM) to visualize data without storing it.

Later, in 2019, Kandah et al. [39] presented a hardware-software co-design approach that includes RF-DNA fingerprinting for devices to have unique identities and behavioral trust management. Liu et al. [40] presented a blockchain-based technique to allow secure routing for Unmanned Aerial Systems (UAS) in mesh networks. In addition, LV et al. [41] proposed a blockchain-based publish/subscribe model for privacy in communication between sensing devices and interested nodes in the network.

Then in 2020, Mohanta et al. proposed a signature storage solution for a diverse set of blockchain-based CPS applications for ensuring trust among the participating nodes in [42]. Beckmann et al. proposed to use blockchain as the trust-enabling system component for Cyber-Physical Trust Systems (CPTS), which is a CPS with IoT enriched with trust as a system component in [43]. Milne et al. further elaborated the CPTS driven by blockchain in [44] by providing formal proofs of properties like integrity, identification, authentication, and non-repudiation using the Tamarin Prover tool.

Afterwards, in 2021, Putra et al. applied a blockchain based decentralised trust and reputation management systems (DTRMS) to various CPS applications, including smart cities, supply chains, and distributed energy trading, in [45].

D. Cyberphysical System Performance and/or Storage

Studies have also been carried out with a focus on solving the performance and storage issues caused by the exponentially growing number of devices and data for CPS systems.

In 2018, Koumidis et al. [46] considered the integrity of CPS record logs for accountability and proposed a blockchain-based approach for computing block resource optimization in the PoW mechanism, including computational cost.

In 2019, Li et al. [47] proposed a blockchain dividing strategy using the community structure clustering method to decrease communication load, storage of dispensable data, and synchronization time. Koumidis et al. [48] developed a

Fig. 2. Statistics of the papers published between 2018 to 2022, with (a) the pie chart according to the major concentration of the paper and (b) stacked bar chart of broad categorization of topics in each of the years.

blockchain technique for securing event logs in CPS, which bundles event data into blocks and delivers them to the system components that monitor and control the CPS in order to minimize the computational resources. Also, in [49], and [50], Masood et al. presented a framework for a blockchain-based distributed management system for closed-loop CPS in order to address issues caused by computational constraints, centralized control, and network dependency.

Then in 2020, Bouachir et al. [51] presented an analysis of a fog-computing-based ecosystem integrated with blockchain for IIoT in order to manage and enhance the data storage, quality of service, and security requirements. In [52], for license-free spectrum resource management in Cyber-Physical-Social Systems (CPSSs), Fan et al. proposed a standard framework using blockchain and smart contracts that can be used for the edge computation of non-real-time data. Also, Isaja et al. reported on FAR-EDGE experimentation of Smart Contracts and Blockchain, which proposed a reference architecture based on edge computing concentrating on efficient distributed computing power and network bandwidth usage, in [53].

Most recently, in 2021, Wang et al. [54] focused on the storage and computing challenges caused by IoT devices used with CPS cloud/edge computing. They proposed a Blockchain Software-Defined CPS (SD-CPS) framework that applies distributed resource management using cloud and edge computing to reduce system delay. Vangipuram et al. proposed an off-chain distributed storage solution in [55] to load massive medical data sets, as well as a blockchain implementation to securely transport data from the infected person to the hospital system via edge technology.

E. Multiple Focus

A few studies from 2021 emphasize a combination of objectives, including security, control, performance, data storage, and privacy. Neelam and Shinray [56] presented an IoT-enabled CPS model using a fully programmable recursive internetworking architecture (RINA) with secure authentication using RINA password authentication for improving SDN and blockchain-enabled security. Rathore and Park [57] addressed the challenges of centralized control, privacy, and security in

deep learning (DL) for CPS. They proposed DeepBlockIoT-Net, a DL approach for use in IoT CPS networks that uses blockchain for DL operations applied at the edge layer for decentralized and secure operations.

F. Cyberphysical System Applications

Finally, other studies focus on a variety of particular applications for blockchain in CPS, including shared manufacturing, smart grid, energy systems, intelligent robots, and Smart Controlled Business Environments (SCBE).

In 2018, Zhao et al. [58] addressed the issues of security and reliability of data distribution services. They proposed a secure pub-sub (SPS) architecture for blockchain-based fair payments with reputation, implemented with Bitcoin, smart contracts and Ethereum network. Wagner and McMillin [59] considered security for VANETs, and presented a improved Bitcoin-based blockchain architecture with physically verified transactions, as well as a protocol for VANET security that does not require assistance from roadside units (RSUs). Teslya and Smirnov [60] proposed a blockchain-based cyber-physical framework for the creation of intelligent robots that are considered separate entities, interacting with each other. Lastly, Dong et al. [61] considered the opportunities and challenges presented by blockchain in uses for developments in energy systems and presented a prototype for future grids, which includes IoT, cloud, and blockchain.

Then, in 2019, Patsonakis et al. [62] also focused on energy systems, proposing a Demand Response (DR) energy system design that uses blockchains and smart contracts for decentralization to ensure security, privacy, reliability, audibility, and resistance to tampering. Gu et al. [63] presented a blockchain-based CPS security and safety protection framework for intelligent manufacturing CPS. Ahmadi-Assalemi et al. [64] presented a framework using federated Blockchain model with a digital Chain-of-Custody (CoC) and a collaborative environment for the CPSs to serve as Digital Witnesses (DW).

In 2020, Kim et al. presented a comprehensive overview of the cyber-physical security vulnerabilities of the battery management system (BMS) from potential cyber-attacks in [65]. In [66], Barenji et al. addressed the security, scalability,

and big-data problems for small and medium manufacturing enterprises (SMEs) by proposing a blockchain-based platform as a trustable network. Yu et al. also addressed manufacturing and proposed a Blockchain-based Shared Manufacturing (BSM) framework for CPS based application support in [67], where the core operations are performed through a Resource Operation Blockchain (ROB). In [68], Moore et al. presented the design and prototype of a blockchain implementation with CPS that consisted of a cluster of microcomputers forming a smart grid. These microcomputers, acting as nodes, are controlled by the smart contracts of a private blockchain. Also, Shu et al. presented a two-layer model for MCPS in [69], where medical records are stored off-blockchain and shared on-blockchain. They also proposed a certificate-less aggregate signature based on a multi-trapdoor hash function for MCPS. Also related to healthcare, in 2021, Rachakonda et al. [70] proposed Smart-Yoga Pillow, a Healthcare CPS edge device that analyzes sleeping habits and physiological changes that occur during sleep, with a focus on the security of data transfer. Product traceability has remained a difficult subject in mass manufacturing. By using the Industry 4.0 Festo Cyber-Physical Factory, Davis et al. present a new Blockchain-based architecture for integrating the processes of a real manufacturing line [71].

V. DISCUSSION

This section provides a statistical analysis of the papers published from the year 2018 to 2022 in blockchain-enabled CPS security and operation domains. Fig. 2 represents the statistical findings of the related publications, specifically Fig. 2(a) illustrates the pie chart of publications according to the major contribution of the paper, and Fig. 2(b) represents the papers according to the publication year. From the pie chart, it is observed that the largest group of the publications are CPS security-oriented, which holds more than 22% of the publications, followed closely by CPS application systems. This research illustrates the wide variety of blockchain applications for CPS, as well as the importance of blockchain in facilitating security in CPS. The CPS Trust papers are holding close to one-sixth of the publications in these years. From the stacked bar chart, it is seen that while there was a continuation of CPS operations centric papers till 2020, as the amount of CPS blockchain research grew significantly, the trend was shifting significantly from the CPS operation focused papers to the CPS security concentrated papers. Also, there is a rising number of papers in the blockchain-enabled domains other than CPS security and operations. While the number of published papers is currently much lower in 2022 than in recent years, it is important to note that this survey only takes into account papers published through the beginning of March 2022.

We also found some interesting trends from reviewing the literature. Among the research studies that propose blockchain-based models for CPS, 24 papers utilized smart contracts, which are a set of agreed-upon rules or terms that run on the blockchain to automate the execution of the terms without

the need for a third party [49]. Of these 24 works, 16 used Ethereum as the open-source ledger platform for smart contracts. Also, 8 of the proposed models use edge networking, and 11 of the models leveraged encryption-based methods specifying the type. A detailed list of related reference papers is presented in Table. I. Another insight is, for efficiency purposes, PoW like consensus mechanisms are too complex for CPS/IoT-based applications, leading to high delays and low throughput [11]. A topic worth considering in future studies on CPS-based usage of blockchain is the inclusion of greater mining incentives [11].

TABLE I

VI. CONCLUSION

The intrinsic combination of distributed data storage, consensus methods, and secure protocol implementations in blockchain efficiently solves diverse CPS performance and security issues. In this paper, we review current research on blockchain-enabled CPSs from both the security and operational viewpoints. In addition, we present some graphical representations of research works that summarize existing studies in an organized manner, which will aid future researchers in focusing on less explored areas.
